RareBooksClub. Paperback. Book Condition: New. This item is printed on demand. Paperback. 46 pages. Original publisher: Seattle, Wash. : Pacific Marine Environmental Laboratory, U. S. Dept. of Commerce, National Oceanic and Atmospheric Administration, Oceanic and Atmospheric Research Laboratories, 2004 OCLC Number: (OCOlc)318607501 Subject: Ocean currents -- Pacific Ocean -- Measurement. Excerpt: . . . Subsurface ADCP Data in the Equatorial Pacific 11 shift in the backscattered acoustic energy from a range set to be 0.5 m to 2.0 m vertically from the instrument. The beam-direction velocities, computed from the measured Doppler shift for each beam, are converted to earth coordinates using the relative transducer orientation and a Precision Navigation compass. The Argonaut-MDs were generally set to collect data once per second for 180 seconds at a 600-second interval. The theoretical accuracy 1 of the Argonaut-MD velocity measurement is 1.8 cm/s and the compass is 2.0. Early tests by PMEL indicated that the Argonaut-MD measurements compared well with coincident ADCP velocities, but later comparisons revealed that the Argonaut-MD horizontal current speed was biased low (Freitag et al. , 2003). Investigation revealed that the bias was due to the inability of the Argonaut-MD compass tilt-sensor (Precision Navigation model TCM2) to function properly on moorings deployed in high current regimes where the instruments experience extreme lateral and rotational accelerations. Beginning in 2001, PMEL began to attach vanes to each instrument to reduce the acceleration of the current meters on the mooring lines. Subsequently, differences between ADCP and Argonaut-MD measurements have been comparable to those found between ADCP and MCM measurements. Vanes were attached to the Argonaut-MDs at 0, 110 W beginning in April 2001 for 7 months, coincident with a nearby, yearlong ADCP deployment. The next deployment of Argonaut-MDs at 0, 110 W was also coincident with the ADCP deployment, but the Atlas...
